Experimental Procedure

Four corn silages (41 to 46% DM) were made August 23 to 26, 1978; treatments were: 1) no additive (control), 2) 8.16 lbs of Cold-flo ammonia per ton, 3) 1.0 lb of Sila-bac per ton, and 4) 1.0 lb of Silo-Best per ton. Silos were opened after 139 days and each was full-fed to 15 heifer calves (3 pens of 5 calves) during a 112-day trial (January 12 to May 4, 1979). The complete-mixed rations contained 88% silage and 12% supplement (Table 19.1). Control silage was supplemented with soybean meal for one group of heifers and urea for another group (urea supplying 33% of the total ration crude protein equivalent). The Cold-flo silage was fed with a milo supplement with no additional crude protein added. Sila-bac and Silo-Best silages were supplemented with soybean meal.

<u>Results</u>

Visual appraisal of the silages showed all were well preserved, and differences in chemical analyses (Table 19.2) were relatively small. Cold-flo silage had the highest pH (4.33) and lactic acid (6.39%), and acid de-tergent fiber-nitrogen was lowest for Sila-bac silage (7.6% of total nitrogen).

Feeding results are shown in Table 19.3. Heifers fed control corn silage + SBM or Sila-bac corn silage had similar performance. Those fed Silo-Best silage had the same daily gain as those fed control silage + SBM, but the latter consumed about 5% less silage. Cold-flo corn silage reduced gains 5% and efficiency 9% compared with control corn silage + SBM, but calves fed Cold-flo silage or control silage + urea had similar performance. Cold-flo silage averaged 11.1% crude protein, which indicates that only about 50% of the Cold-flo nitrogen applied to the fresh crop was in the silage when fed. The relatively high DM content (44%) of the fresh crop probably explains the relatively low recovery of Cold-flo nitrogen.

Each additive reduced fermentation DM losses approximately 3 percentage units (Table 19.4). Ensiling temperatures showed that Cold-flo sharply

³Silo-Best is an enzyme product of Cadco, Inc., 10100 Douglas Ave., Des Moines, IA 50322.

lowered temperatures after day 2; Sila-bac kept temperatures 2 to 10° F below control after day 1; and Silo-Best silage had a lower maximum temperature than control silage (109.5 vs. 116 F), but average temperature of Silo-Best silage the first 35 days was slightly higher than the control silage temperature (Table 19.5).

Stability of the four corn silages when exposed to air on feedout is shown in Table 19.6. Sila-bac silage was more stable than control silage; Cold-flo and Silo-Best silages were not. Temperatures did not rise, and no spoilage was observed in either the control or Sila-bac silages the first 8 days; DM losses were still about 2.7 and 4.4% on days 3 and 8, respectively. Silo-Best silage had initial temperature rise on day 2 compared with day 7 for Cold-flo silage, but Cold-flo lost more DM at day 8 (13.31 vs. 10.38%) and day 17 (25.86 vs. 16.45%) than Silo-Best.
