## Efficacy of Lumax EZ, Atrazine, Acuron, Armezon, Sharpen, Outlook, Verdict, and Prowl H<sub>2</sub>O in Irrigated Glyphosate-Resistant Corn

*R. Currie and P. Geier*

### Summary

All treatments provided statistically superior control of Palmer amaranth compared to the control or a single application of glyphosate. All treatments provided excellent control of all other weed species. Although all herbicide tank mixes elevated corn yield compared to the control, there were no statistically significant differences among herbicides in their ability to do so.

### Introduction

Bicyclopyrone is a newly labeled active ingredient in the herbicide tank mix Acuron (bicyclopyrone+mesotrione+S-metolachlor+atrazine+the herbicide safener benoxacor). Acuron is basically the long-used tank mix Lumax EZ (S-metolachlor+mesotrione+atrazine+the herbicide safener benoxacor) with the addition of bicyclopyrone. The Syngenta Corporation is marketing this herbicide as an improvement on Lumax EZ, with broader weed spectrum and greater control consistency. The local price of this tank mix is unknown at the time. To allow producers to make informed purchases, comparisons need to be made to other standard tank mixes. It was not possible to test this new product directly with all competing products. Only a small subset of products was selected. Results should be compared to those of other products before purchasing.

### Procedures

An experiment at the Kansas State University Southwest Research-Extension Center in Garden City, Kansas, evaluated weed control in irrigated corn with Acuron, Lumax EZ, Armezon (topramezone), Sharpen (saflufenacil), Outlook (dimethenamid-P), Verdict (dimethenamid-P+saflufenacil), and Prowl H<sub>2</sub>O (pendimethalin) tank mixtures. The entire experimental area was overseeded with a mixture of shattercane (rox orange), green foxtail, and crabgrass seed. The kochia, Palmer amaranth, and Russian thistle populations were natural infestations. Glyphosate-resistant corn was planted May 7, 2014, and preemergence herbicides were applied on May 9, 2014, using a tractor-mounted, compressed CO<sub>2</sub> sprayer delivering 20 gpa at 4.1 mph and 30 psi. Postemergence herbicides were applied July 2, 2014, with a CO<sub>2</sub>-pressurized backpack sprayer delivering 20 gpa at 3.0 mph and 27 psi. Soil was a Ulysses silt loam with 1.4% organic matter,

pH of 8.0, and cation exchange capacity of 18.4. Plots were 10 by 35 feet, arranged in a randomized complete block with four replications. Weed control was visually rated on August 21, 2014. This was 104 and 50 days after preemergence and postemergence treatments were applied, respectively. Corn yields were determined October 31, 2014, by mechanically harvesting the center two rows of each plot and adjusting grain moistures to 15.5%.

## Results and Discussion

Weed pressure was very intense for Palmer amaranth, green foxtail, and crabgrass. Weed pressure for Russian thistle and shattercane was adequate. All treatments provided statistically superior control of Palmer amaranth, compared to the untreated or a single application of glyphosate. All treatments provided excellent control of all other weed species. Although all herbicide tank mixes elevated corn yield as compared to the control, there were no statistically significant differences among herbicides in their ability to do so. Because the weed control of all treatments was excellent, this study does not define the added value that bicyclopyrone adds to the various tank mixes. To understand how to best use this product, its price must be determined and further research is needed.
