Educators must develop a “computer strategy” to cover all potential needs of their district.

## The Computer System: Developing a Plan for the School District

by David S. Honeyman and Janice C. Honeyman

Educators have come to accept the computer as a “fact of life” in American society. When confronted with the probability that by the year 2000 half of all jobs in factories and offices in the United States will be affected in some way by changes in office automation and information processing, many school districts are beginning to develop computer programs for their students. While the business community continues using computer technology to streamline operating efficiencies and increase effectiveness within its organizations and develops new information management technologies, many educators are only beginning to implement instructional programs related to these new, powerful tools.

Many school systems throughout the United States are struggling with issues concerning the computer technology and computer literacy programs, but most educational leaders are unfamiliar with the constantly changing terminology and technology as they apply computer utilization. While some principals are familiar with given operations and certain uses of the computer, few have a feeling for the totality of the problem as it relates to the successful implementation of computer technology within their schools.

We have many examples in education where technological innovations were introduced into school systems without proper planning and sequencing of their implementation. Educational TV, reading machines, self-directed and programmed learning projects were expensive failures in many schools. The computer, however, is not simply a technological innovation. It is rapidly becoming an instructional discipline—English, math, computer science, etc. As a result, school systems are confronted with the problem of instituting instructional programs which will teach children not only how to use this new technology, but how it works as well.

Models constructed as guidelines for the development of data processing and information management facilities in business (Gibson and Nolen, 1975) can be applied to the educational setting in order to help educators visualize the process of establishing a computer “system” for their schools. The term “system” is not meant to imply that one arrangement, large or small, one type of computer, IBM or Apple, will be the best for all situations. Likewise, use of the term system is not meant to imply that 20 microcomputers in various school buildings be networked together. It does mean, however, that a school district must have a plan directed to the total picture of its computer needs for instruction, communication and administration. Educators must avoid limiting themselves to single function applications, such as teaching computer logic, programming languages, or word-processing. There must be a comprehensive plan which covers all aspects of intended computer use in the school. They must develop a “computer strategy” to cover all potential needs of their school district.

Brantly R. Allen, professor of accounting and computer applications at the Colgate Darden Graduate School of Business Administration writing in the unpublished monograph, “Computer Strategy: A Philosophy for Managing Information Processing Resources” (1982) noted the following:

This is the 13th year of business use of computers, ... what accounts for sustained success with computers in some firms and failure in others? Only rarely are technical factors the brilliance or blunder of individuals the explanation; instead, the primary determinant of continued success in the use of computer technology is almost always the quality of one's strategy, policies, practices and techniques for the management of the technology ... too often businesses (schools) simply do not know what a computer strategy is or why it's necessary.

The planning process for computerization within the school district should follow patterns similar to that of any management control system. Such systems usually include consideration of the following: environmental and institutional assessments; strategic planning and decision making; and defining the control system to be used for project evaluations (Allen, 1982). While the technology and applications exist which will facilitate the development of any and all types of computer systems without a comprehensive plan and set of management practices aligned with that plan, the introduction and effective use of computers within the organization may fail (Withington, 1981). Figure 1 summarizes these stages as they might be applied to a public school setting. Details of the processes involved are discussed below.

### Assessments

**Planning to plan and the decision to implement** During the initial stages of the planning process it is important that members of the steering committee be identified and given direction by the superintendent. The decision to implement programs utilizing computer technology must be made early in the planning process, and school districts must be willing to pay the price, both in dollars and in effort, to guarantee a successful program. Membership on the steering committee should be kept to a minimum and should include...
Environmental Assessments: Many educators currently express the opinion that computer literacy will be a necessary skill for future employment. As seen above, the use of the computer is expanding within the business world, and our young people have a right to expect that their educational programs will prepare them for the future. But what will those needs be? Will office employees and factory workers need to know computer logic, or Fortran or Cobol? Will they need to know about interactive uses of the computer and artificial intelligence, or will it be more important to know how banks produce their monthly statements, and how prices are recorded at the grocery store with the universal product code and optical mark reading equipment? School districts must determine which aspects of the new technology are important for their students, as they enter the working world or go on to further education.

These needs will vary from location to location. Industrial and urban settings will offer different opportunities for young people than rural, farm environments. The needs of college bound students will differ from students entering the work force at the completion of their high school education. A comprehensive assessment of such needs should indicate the nature of the instructional program for the district.

A vocational education center which began a data processing operations several years ago is having trouble placing its graduates. While their students are excellent programmers in Cobol, many new business installations use newer fourth-generation data base languages which no longer require maintenance programmers. This has reduced the number of available jobs in this field. New technologies have created the need for new skills and this center has not kept pace. As such, these environmental assessments, which must be continuously monitored, indicate the overall needs of the students and help clarify the responsibility of the schools to provide for those needs. The results of these assessments will outline the types of courses needed for the instructional program and the applications which are to meet those recommendations. This will form the instructional component of the application strategy.

Institutional Assessments: As an operating entity, the school district itself can benefit from the efficient and effective use of the computer. Once an external assessment indicates those programs needed for the benefit and well-being of the students, one can look at the school system and define its goals and objectives such that the computer can assist in its daily operations. Such an evaluation would include questions of community and parent communication, teacher perceptions of the use of the computer for instructional management programs, and building principal assistance for many of the daily business and record keeping problems associated with operating a school. Such an assessment would show needed information flows required to maintain daily transactions and detail the types and quantities of data involved. An accurate and detailed picture of data flows in and through the school district provides later planning groups, i.e., the specific planning groups, with information which will form the basis for the data strategies and administrative applications to be developed later in the planning process.

Another large school division realized that the computer could provide accurate and concise data on their attendance figures and decided to contract with a local computer service center to provide such a service. It was assumed that such an arrangement would
greatly simplify the record keeping and reporting required by the state. A bright and industrious data processing manager made assurances that this project was basically simple and guaranteed it success. However, there was no plan or time sequence developed for this project. The following September building principals were informed of the new system and told that they would participate. They had not been consulted or informed and there was measurable antagonism toward using the new system. By Christmas that year, the October attendance report was still incomplete and by March everyone was doing his or her year's attendance figures in order to prepare the year-end report by hand.

**Strategies**

During this phase of the planning process, details of the various strategies to be used during implementation are developed. This includes analyses of the applications to be used and developed for both instruction and management, the data needs of the organization and the control mechanisms which will be implemented for accountability and as measures of performance. In addition, the technology required to do those applications will be evaluated. Herein lies the key to a successful schoolwide computer system. Since most school districts will have varying needs and expectations for their system, the planning phase must incorporate as many of these variables as possible. A single, unified systemwide strategy must be developed.

A school district of approximately 10,000 students bought 12 microcomputers for its middle schools. Due to a lack of planning and control over this project, individual building principals received equipment from a variety of vendors and simply gave the units to their teachers. What followed was an attempt by the school division to teach teachers how to use these new "toys." However, few teachers were interested in learning how to use them, and since there was no one at the building level interested in developing applications and using them, they were soon relegated to storage and used primarily for games during free time. Had there been a detailed plan for introducing these computers in the schools, the results would have been different.

**Applications Strategy:** Following the guidelines noted by the environmental and institutional assessments, the school system planners must question applications: for what reasons will the computer be used and how? Here the specific planning groups assigned by the steering committee must investigate the thousands of uses to which the computer can be applied. Decisions must be made concerning which applications will be used for (1) instructional purposes, and (2) operations and management.

1. **Instruction:** How will we design our K-12 instructional program? Do we need to develop scope and sequence charts for the new computer curricula in order to avoid duplication and allow teachers to monitor the effectiveness of various aspects of the program? Do we want to teach programming and computer logic? Do we want to play games? Do we want teachers to include computer use in the regular classroom, such that the teacher sets up an "answer sheet" and students feed in data from science experiments, math problems, or questions of English sentence structure, and process the numbers to get a result? Are we concerned with delivering courses covering computer literacy to all students and, if so, how do we define literacy?

2. **School Operations:** Usually the benefits of microcomputers in assisting with the daily operation of the school go unrecognized. Word processing can facilitate the preparation of announcements, newsletters and attendance lists. Accounting packages and spreadsheet can assist in the maintenance of general ledger and fund accounts, and the various reports for pupil enrollment, transportation, etc., can be generated, stored and updated. Trends in test scores and other measures of "accountability" can be developed and used for analysis of student performance at the classroom, building and district levels.

Again, the school system must decide what it needs and the planning groups must detail these expectations.

**Data Strategy:** The need for a data strategy is apparent when one considers the number of reports which must be processed by the school district almost daily. Some of these were mentioned previously, and it is important that the computer system be able to meet these user needs. If the production of designated reports or the generation of certain student records is done easier by hand, obviously the computer will not be utilized. Likewise, if the information generated is not constant and relevant, it will be of little use to those who will receive it. A school district planning to automate its administrative functions must perform a thorough investigation of all possible sources of data being generated within the school district. Such a "data audit" would include detailed descriptions of the data requirements from each of the districts functional areas including attendance, student records, food service, bus scheduling, student and athletic activities, personnel, purchasing, etc. Following the definition of these data descriptors, the flow of information for the district can be mapped and appropriate computer applications designed.

**Organizational Strategy:** The organizational strategy must answer questions similar to the following: If the computers will be purchased by the school system, who assumes ownership of the equipment? How will the equipment be configured and who will financial support be allocated? Who is responsible for hardware maintenance and expansion (new disk drives, modems, printers, cards, expanded memory, etc.)? Who is responsible for renovations to existing facilities? Will the district purchase existing commercial software, or will custom software be developed? If custom software is to be developed, who will do the job, and who will write the software specifications. In addition, questions must be asked concerning room schedules and the location of the computers, how many students will be using them, and what utilization rates should be expected (hours of computer time per day). How will the district train its administrators and teachers? How will the district adapt to the changing role of the teacher? Will differentiated staffing plans evolve around computer technology such that the master teacher becomes the manager?
of a technological classroom with 30 to 40 students participating in computer assisted instruction? These and other questions must be answered by the organizational strategy.

District administrators must be made aware of the expenses associated with the development of a computer system. The need for intensive planning is obvious when considering the purchase of a $200,000 IBM system 4300 for business operations and financial analysis. However, buying little “Apple” computers for the schools appears to be a relatively uncomplicated project. They cost about $1,000 each, and most high school principals could afford to purchase several from general funds without going to the central administration for approval. But the purchase of the computer is just the beginning of the expenses associated with its operation. It is quite easy to spend an additional $5,000 to $8,000 on add-ons: packaged software, a printer, a plotter, additional memory, etc. It is not uncommon to hear stories of individuals with limited computer experience who have purchased a basic computer for $2,000 and within six months have spent an additional $5,000 on the system. Proper planning and detailed organizational strategy are necessary to avoid unanticipated expenses that can destroy a viable, ongoing project.

Technological Strategy: Controlling the growth and proliferation of microcomputers in the schools and giving direction to a growing computer system are important considerations in choosing technology. The availability of repair and technical assistance is often a controlling factor in the type of hardware to be purchased or leased. Problems which arise from regular use of the computer must be remedied quickly or users will avoid developing new programs for fear that the “thing” will be down when they need it most.

Extensive research must also be done to match the expressed needs of the school district with available technology. It must be realized from the beginning that there are major incompatibilities among software packages and different computers; there are even many subtle differences in machines within the same computer manufacturer.

One principal bought a personal computer with a printer and a popular software package to assist him in preparing data and developing graphs concerning student performance in various special projects occurring at his school. He soon discovered that he could not analyze the data but could not print it without another special software package. In addition, he found that his printer did not do graphics unless he installed a special “card” in his computer.

In general, standardization of software programs is very low, and, whereas one may think they will do similar tasks, in fact, they do not. Of 10 faculty members at a major graduate business school who currently own personal computers, there are seven different word processing packages being used.

The computer system must provide guidance and leadership for the users. Just as schools have an instructional plan which includes curricula for the selection of textbooks and instructional materials, the computer system must be developed with the users in mind. The technological strategy must consider present and future uses, expandability, and the computer’s capacity to be applied to a variety of situations, i.e., its flexibility. Too often computers are purchased with a limited purpose in mind and once that level is obtained no growth occurs.

Control

The term control means different things to different people. The computer system must be controlled. Applications must be governed, new purchases approved and priorities set. There must be periodic review of the system in order to monitor its growth and development. Results must be measured and evaluations done on a continuing basis. In order to do this, responsibilities must be assigned. Users must be aware of the totality of the program and its sequencing, from elementary to high school. They must know the expectations and ways in which the program will be evaluated. Criteria for ongoing evaluation can include measures of efficiency, cost, student effectiveness, numbers of students educated, and utilization rates hours/week/school, but teachers and administrators must be informed.

User groups should be developed under the leadership of individuals in a position to provide assistance and guidance. Usually this will be the building principal. As instructional leader of the building and its programs, this person must assume the leadership role. It is through this office that requests will be made for additional software and similar equipment. Class schedules will have to be adjusted in order to allow students and teachers access to the computers. Teachers will have to be given time to practice and learn about the uses of the computer, all of which will require the support and approval of the principal.

The computer “system” within the school must be encouraged and supported by the staff member. Four or five teachers in various schools cannot make a system. They can be the principal users and faculty leaders in the use of the computer, but success will be dependent upon total faculty involvement and cooperation. This can only be guaranteed by supportive administrative personnel.

Implementing and operating a computer system can be a challenging experience. The benefits of such a system are difficult to measure, and the costs of bringing the system up and running can be more than many districts can afford at one time. A detailed plan can indicate sequences and phases for implementation of the project over a given period of time by showing at which grades the system should be started and the costs associated with each step in the process. Proper planning and phased implementation of the project can assure greater levels of success than previously thought possible.

Structuring a computer system simply asks: What do we want to do? What are the needs of students, teachers, and administrators which must be met? Who will be doing it? And, what technology do we need to do it? Without a computer strategy and proper controls to govern its operations, structuring, the program within the schools and resolving problems and conflicts can lead to insurmountable obstacles which can destroy the project. Without a comprehensive plan, the only “winners” will be the computer manufacturers and salespeople—and the losers will be the students.

Internalization ... must take place if the innovation is to become part of daily schoolwork.

Training, Computers, and Educators

by Richard A. Diem

In the past three to five years schools in all parts of this country have invested millions of dollars in a technology that holds untold promise in its ability to deliver information in a palatable, easily manipulable, and nonthreatening mode. So great has the persuasive and enticing manner of this technology been that school administrators, without much experience in the technology or the ramifications of its purchase, have convinced both school boards and the public at large that the use of computers will dramatically change literacy rates and, at the same time, offer students a utilitarian tool they can use when they leave school.

The final results of these dreams are not yet in and probably won't be until this generation reaches maturity. What we do know is that the computer as an interactive instructional tool for school use may not ever reach its potential. Despite the number of states that now mandate computer literacy as a high school graduation requirement, and those that include courses in computer training as a part of teacher pre-professional training, there are signs that nothing has changed in the majority of American classrooms. In a recent article in the Phi Delta Kappan (December 1984), Alfred Bork pointed out that "Most learning is still taking place through passive learning modes that have been dominant for hundreds of years: books, lectures." Bork rests most of the fault on poorly designed computer software and the lack of interactive training in computer usage. While these issues need immediate and long-range solutions, a third problem, that of classroom application, bears both scrutiny and study if the full potential of current and future technological advances finds its way into elementary and secondary schools.

Application, by its nature, requires one to use learned materials in new and concrete situations (Bloom, 1956). In terms of computer technology, this means that the classroom teacher must learn how to apply the hardware, software, and computer languages to specific classroom situations. A knowledge of the technology, itself, will not suffice for very long. The practical, everyday, instructional applications of computer technology will have a greater effect than surface usage of the computer for one or two hours per week.

Richard A. Diem is an associate professor of education at the University of Texas at San Antonio.

Colleges and universities in an effort to provide catch-up training in computer technology have offered to teachers coursework, in various formats, at both the pre- and inservice levels. Most of the classes have concentrated on hardware, familiarization, introduction to BASIC, and evaluation of software. While these efforts serve a useful purpose in orienting the novice user to computers, they do not provide the type of application study that, in the long run, will show teachers how they might actually use computers as part of their repertoire of classroom pedagogy.

Instruction in curriculum design, development and evaluation must accompany technological training. Working together, the practitioner can take the content of computer coursework and interweave it within subject matter. Construction of long-range developmental patterns of instruction with technology as an adjunct pedagogical mode could then ensue, instead of the types of current computer classroom efforts that are based on software availability and willingness to bend curriculum to meet hardware-time requirements.

The training of teacher-designers would begin to alleviate some of the problems of poorly constructed software. By providing practitioners the ability to develop solutions to their own, classroom specific, instructional problems, not only would the usefulness of technology improve, but the teacher's entire methodological repertoire would gain immediacy, in terms of feedback and evaluation concerning software, would ensue at a faster rate and perhaps more productive rate. Classroom specific software, long thought of as impractical, could begin to be developed under this type training scenario. Not only would coursework of this type provide teachers with direct access to the developmental aspects of instruction, but, if done correctly, also improve quality of instruction.

This type of training would include development-orientation needs assessment tools to determine class and individual instructional needs both in content and technological areas. It would also emphasize an understanding of subject matter so that proper instructional designs, in terms of when to use the computer, could begin to take place. Evaluation, an afterthought in most classrooms, would also have to be improved if any positive measures of instructional performance were to be collected and analyzed.

The kind of academic efforts mentioned above are not pie-in-the-sky dreams. They are based on long-standing successes and failures replete in the history of American education. Internalization, in terms of a practitioner's understanding and usage of technological innovation, must take place if the innovation is to become part of daily schoolwork. If this does not occur, in some manner, in the next two years, the schools will turn away from computer technology much as they did 20 years ago when television, then a current video technology, was consigned as a baby-sitting device to be used on rainy days. A tool as powerful as the computer should not be thought of as simply a tool for mathematics, special education or word processing. Instead, it must be looked at as a device that can aid in education's basic goal-increasing understanding and knowledge.

The forces that contributed to specialization and diversification are changing.

The Development of Higher Education Administration as a Profession

by Vineta S. Belden, Helen G. Cooper, Samone L. Jolly and James L. Sand

Historical Background

The development of higher education administration as a profession is a concept that evolved in recent history. With the exception of the office of the president, the idea of an individual fulfilling a purely administrative function within an institution of higher education was rare in this country until the end of the 19th century. Even then, the presidency was not totally administrative until late 1800s; prior to that he was not only the administrator, but also the primary teacher. (23)

Near the beginning of the century, various factors affecting higher education began to surface. These factors, in turn, had an impact on higher education administration. The impact was two-pronged: specialization and diversification. Specialization refers to the increasingly narrow focus of each individual's function within the institution. Diversification implies that there is an increased number of functions undertaken. The dual impact is easily observable; however, the factors that prompted the change are more complex.

Specialization grew to meet the increasing complexity of higher education in general. Diversification, on the other hand, came as a result of institutional changes.

Factors bringing about increased specialization include an ever increasing number of people attending higher education institutions, the expansion of knowledge, and government involvement in higher education.

Relative to the increasing number of students, the most obvious reason is the increased population. As John J. Corson pointed out in The Governance of Colleges and Universities, "the population of college-going age...grew approximately 50 percent from the years 1939 to 1969 and another 10 percent in the three years after that." (12) Not only did the size of the population grow, but the percentage of people within that population attending institutions of higher education also grew, along with the idea that all young people should have the opportunity for an education beyond high school. Coupled with this contention was the concurrent belief that graduating from a four-year institution would bring increased socioeconomic status. (23)

The expansion of knowledge is demonstrated by the transformation of college and university faculties. The early American colleges had a small faculty, generally recent graduates who stayed for a few years before moving on to permanent positions. They taught all subjects, and for the most part, stayed with a single class for four years. (10) As the body of formal knowledge grew, the number of faculty increased and changed from young generalists to ambitious, research-trained holders of the Ph.D., who were determined to make permanent careers of their academic disciplines. For example, by 1981, Harvard had reorganized into 12 divisions, each of which included at least one department. (41)

Kazell and Ginsburg (23) concluded that all institutions and corporations are greatly affected by government involvement and regulations on all levels, and that institutions of higher education were not exception. They pointed out that the latter are even more affected than most in several areas. The most obvious is funding, ranging from direct state funding to public institutions, to state subsidy programs for independent institutions, to financial aid programs that give indirect benefits to the institutions of their choice. (8) Other areas of government involvement cited are approval of programs and degrees, chartering of institutions, affirmative action involvement, in staff and student affairs, access provision for the handicapped and graduate assistantships. (23)

Alan Pifer in "The Responsibility for Reform in Higher Education." (12) describes our universities as "gigantic service stations principally for government and the larger corporations. He enumerates 13 functions which universities have been called on to perform, few of which are related to academics while others have no logical associ ation with higher education, but have become expected services. These conditions have created a need to establish and administer functions that did not exist in the past. This, coupled with the rapid development of higher education, explains to some extent the problems of today.

The forces that contributed to specialization and diversification are changing. These changes are affecting, and will continue to affect, the development of higher education administration as a profession. First, enrollments, in general, have stabilized or decreased. This is due to both the shrinking size of the population of typical college-aged students and the diminishing of the belief that a diploma from a four-year institution is the way up the socioeconomic ladder. An increasing number of people are <=community or technical colleges as better long-range alternatives that get them into the job market faster with less financial investment.

Declining enrollments also caused a struggle for survival in smaller institutions and major efforts to temper losses among larger schools. Stiffer competition among institutions has arisen as each tries to maintain previous levels of enrollment. This has strong implications for higher education administration. Institutions which are unable to stem this tide may find themselves with administrative departments exceeding current needs. Whereas specialization had been both a necessity and a luxury during the high-water mark of enrollment, it may now be necessary to

Vineta S. Belden, Helen G. Cooper, Samone L. Jolly and James L. Sand are graduate students at Kansas State University, Manhattan.
cut back during recession. As a consequence, an administrator who formerly had a narrow full-time field of responsibility may now be asked to broaden that scope and perform duties once assigned to others. Flexible administrators will adapt; others may be in precarious positions as the institutions attempt to consolidate positions to reduce expenditures.

Although specialization will tend to decrease, diversification, on the other hand, will remain stable or probably increase to meet the new consolidated functions. In addition, some department's undertake functions not previously attempted, in order to maintain department size.

Overall, higher education administration will be less characterized by specialization. But, individual administrators, along with institutions, will continue to diversify in order to preserve the status quo.

Stages of Program Development

The first stage of program development of the graduate educational administration curricula begins with the first quarter of the 20th century. In its early development, the focus of the curriculum was primarily on the practical content, featuring information about educational policies in cases where administrators needed common understanding for implementation purposes or specific problems of practice. As programs grew, concepts were borrowed from other disciplines. The concept of “job” became the critical focus for studying administration—dividing the job into different functions and organizing work to increase efficiency were the key considerations. For example, job orientation using the industrial administration model was copied by educational institutions of higher learning into curriculum content, e.g., Luther Gulick’s planning, organizing, staffing, directing, coordinating, reporting, and budgeting. Graduate students and professors spent much of their time researching practical problems.

In the second quarter of the 20th century, the focus of study and training shifted from the jobs to people. Human relations emerged from the research findings of informal activities within various organizations. An example, is the “halo effect” from the Hawthorne study on the productivity. These findings stimulated research in order to find solutions/answers to this phenomena and later led to formal studies concerning human behavior in the work environment.

By the 1940s, democratic administration was highlighted in books and widely expounded in programs as well as practice. The emphasis was on functional tasks and human relationships. Job functions became content within curricula as personnel management, school-community relations, business management, curriculum development, and supervision, ideas, such as “individual worth and dignity,” were stressed.

The “new movement” of the 1950s began to impact on administrator preparation from the major research institutions, especially in the United States, Canada, and Australia. The move toward the “science of administration” as a goal to the production of effective theories of administration prompted research to study descriptions, explanations and predictions about administration and organizational behavior. More social science content was incorporated into the administrative program of study, as well as reality-oriented materials used with case and simulation situations. The focus moved away from the administrator as a human-relations expert to one of the administrator needing to be a skilled analyst who used theories of groups, organizations and communities in order to cope with management tasks and challenges. In other words, the “new movement” embraced the concept of “administration qua administration,” whereby administration was viewed as similar in all organizations—educational, business, government, etc. During the 1960s, the “what is” theory continued. But, practicing administrators began to challenge this simplistic approach to the complex problems they encountered. In turn, professors began to question the appropriateness of this model. The difficult policy issues in society during the late ‘60s and early ‘70s moved the emphasis to organizational missions and environments focusing on their uniqueness.

In the 1970s, research began to be more diverse. Qualitative and inductive approaches to knowledge development were being seen as appropriate processes in administration. Organization development continued to be the theme for research studies. The specific question in the late ‘70s as studied by Daniel Griffiths and others, was “what knowledge is most valid and useful to those studying and practicing educational administration?” As the 1980s emerged so did a pattern of pluralism. Knowledge in administration began to change to the viewpoint that administration content and/or practice was self-limiting in terms of scope and transferability, especially in the educational, societal and cultural contexts.

The impact of the “new movement” continues into the 1990s. This is particularly true of doctoral programs in the United States. Administrative theory courses are frequently offered within most of these preparatory programs.

A new meaning of management is emerging out of the cyclical systems theory. Adam Smith contends that formal organizations are (or are like) a giant computer with its input and output, its feedback loops, and its programs. This machine—the organization—is in turn guided by a servomechanism—the techno-administrative elite. Education is now moving toward mass education through the use of computerized instruction in the classroom.

Trends

The trends influencing educational administration preparatory programs are basically four: population, internationalization, societal change, and external agencies offering inservice training. The population dynamics continue to influence schools (birth rate growth and decline causing overabundance of programs developed in the ‘60s and ‘70s). Today, this makes the challenge one of preparing fewer administrators more effective. The second trend affecting preservice educational administration is the internationalization of education administration. Organizations such as the Commonwealth Council for Educational Administration, the European Forum on Educational Administration, the Inter-American Society for Educational Administration, and the University Council for Educational Administration, have diffused administrator study and preparation worldwide. Journals (e.g., Journal of Educational Administration and Educational Administration Quarterly) have also influenced this diffusion. The third trend is the one of unusual societal changes which force leaders in education to update and redesign preparatory programs to meet the resultant needs created. The fourth trend is the increasing number of external agencies creating inservice training. As professional organizations grew and matured, they began to assume greater responsibility for filling the gap between preservice and practice. This is due to the criticism by prac-
titioners of the "utility of training programs in preparing
them to deal with the realities of managerial work and po-
tential radical changes brought about by technological ad-
vances." (13, 17, 24, 28, 44) Basically, the complaints focus
on three features of preservice training:
1. Lack of graduate faculty with public school admin-
istrator experience.
2. Lack of application of theory knowledge to actual
situations.
3. Lack of theory relevance due to non-usage of practi-
tioners in teaching/course development. (13, 17, 24,
28, 44)

Management Theories Adaptable
by Higher Education Administrators

Until the 20th century, management functions were pri-
marily performed on a small scale basis. Management was
not a major topic of concern. However, the increasing num-
ber of managers and complexities in management created
by the industrial revolution led to the development of man-
gement theory.

Rausch (33) outlines the evolution of management the-
ory from four major foundations: management science, the
behavioral sciences, the management cycle, and manage-
ment by objectives. Management science, whose estab-
ishment as a separate discipline is credited to Frederick Taylor,
concentrates on the efficiency of the way the individual em-
ployee performs tasks. The behavioral sciences, which de-
veloped considerably later than management science, ex-
amined the way people behaved in their work environment
and the influence their behavior had on the amount and
quality of work output. The management cycle deals with
how to make the manager's work more effective so that the
people who report to the manager will achieve improved
results. Management by objectives is an outgrowth of the
management cycle that deals with the supervision of goals.
It is a significant refinement of, and in some major ways sup-
ersedes, the management cycle, although many managers
today view it as an independent concept.

The Theory Z technique developed by William Ouchi,
builds on all four foundations and uses them to create a
comprehensive framework to provide guidance for adminis-
trators in higher education who want to improve the per-
formance of their units. Theory Z management is a model
for positive administrative change.

The higher education administrator must thoroughly
understand the management concepts discussed in order to
apply the appropriate concept to match his or her leader-
sip style. Application of the appropriate management con-
cept to leadership style can be a foundation for achieving
effectiveness and excellence in the organization.

By the turn of the 20th century, leadership in American
public education had gravitated from the part-time educa-
tional evangelists who had created the common-school sys-
tem, to a new breed of professional managers who made edu-
cation a lifelong career and who were reshaping the schools
according to canons of business efficiency and sci-
entific expertise. The educational administrators of this
progressive era had an interest in moral and civic training,
a passion for efficiency, and a desire to combine new bureau-
cratic techniques with traditional ideals of character. (42)
Instead of trying to mobilize local citizens to act, the 20th
century administrators sought to take schools out of the
political arena and to shift decision making upward and in-
ward in hierarchical systems of management.

In the fall of 1910, America was captured by a new idea
that came out of the nation's capital. That idea was a new
system of industrial management known as "scientific man-
gagement," developed by Frederick Taylor. As early as
February 1911, educators began responding publicly to the
demand to apply scientific management to school admin-
istration. One of the leading educational administrators in the
period between 1915-1934, Ellwood P. Cubberley, dean of the
School of Education at Stanford, described the emer-
gence of scientific management and of educational effi-
ciency experts as "one of the most significant movements
in all of our education history." Cubberley added that this
movement would "change the whole character of school
administration." (10)

Higher education experimented with the succeeding
management approaches, applying information technology
and automation, management by objectives (MBO), modern
organization theory and contingency theory. But by the
1960s and 1970s, administrators began to wonder who con-
trolled the university/college system. Administrators did
not know how to behave. During the 1970s, existing man-
gagement techniques and applications appeared inadequate
to cope with declining productivity and deterioration of em-
ployee morale and motivation. Management practitioners
and philosophers continued to search for a better approach
to solving today's complex organizational problems.

Currently, the Theory Z style appears to have positive
aspects. Its principal objective is developing an organiza-
tional characteristic with a cohesive culture. The organiza-
tional style is an adaptation of the human relations process.
There is an organizational climate of caring, support and mutual
trust. The result of this humanistic element is greater pro-
ductivity and increased employee satisfaction. Theory Z
is often used in higher education, challenges the tradi-
tional static notion of authority and provides a model for
positive administrative change for the 1980s (Redinbaugh and
Redinbaugh, 1983:0.30).

Leadership Skills: 1985 and Beyond

In the past, leaders have often simply emerged. They
have drifted into positions of leadership or have been
drafted for leadership roles. Raffles on emergent leader-
sip is no longer sufficient. More highly organized and de-
liberate attempts to develop leadership are called for. Lead-
ership development programs are often sponsored by local
governments, school districts, business organizations and
institutions of higher education.

Prospective leaders are taught what is known about
leadership through the use of diagnostic instruments in
an attempt to ascertain a participant's management/lead-
ership styles, personality characteristics and psychologi-
cal attributes, etc. Cunningham (16) describes some of
the leadership skills that can serve as valuable aids of
leadership/management in the future:

1. Focusing on the present and future simultaneously
   —dealing with change.
2. Appraisal skills—ability to pass judgment on a
   range of matters.
3. Managing symbols—behavior creates images in
   constituencies that become basis for appraisals.
4. The leader as teacher—know the mission, goals
   and objectives and teach them continuously.
The Presidency

The presidency, the highest administrative office on a college or university campus, should represent the ultimate and best indicator of where higher education administration is heading. To better understand the role of president, it is necessary to again reflect on the history of higher education, its growth, historical changes, societal developments, and the economy.

Using Kansas State University, one of the first land-grant universities in the country, as an example, its choice of presidents mirrors this history. The first three presidents—Denison, Anderson, and Fairchild—were ministers; the next nine—Will, Nichols, Waters, Jardine, Farrell, McCain and Acker—with the exception of Milton Eisenhower—were primarily academics who worked their way up through the ranks of first faculty member, then department head, and eventually dean or other successive administrative or leadership positions. (11, 43)

The levels of administration have remained basically the same; State Legislature and governor at the top; Board of Regents next; president reporting to the Board of Regents; and across the organizational chart, academic and support staff. On the academic side of the traditional provost or vice-president for academic affairs leads deans and department heads below with little change. The difference has occurred in the support staff area—vice presidents for business, student affairs, facilities and numerous levels below to provide accounting, personnel, housing, legal and counseling services. The numbers and levels have multiplied. (7)

The dispersion of power from the president has resulted in the present reassessment of the position. Comments such as: "omnipotent to impotent," and "minister to manipulator" are becoming realistic definitions or descriptions. (26, 28, 46) The emphasis on knowledge of business and management practices, fund raising, and communication is consistently promoted, indicating that the president and university leadership is going farther away from the academic background to the professional administrator. (18, 26, 27, 29)

How true is this contention? Kansas State University is again seeking to fill the position of university president. The advertisement and position description is asking for someone who can:

"...articulate a vision of what the university can be in the coming decades...inspire public confidence...communicate...an appreciation for the appropriate place of instruction, research, student recruitment and retention, cooperative extension and intercollege athletics...present evidence of exemplary leadership...include accomplishment in human motivation, strategic planning...possess scholarly academic credentials; an earned doctorate or appropriate terminal degree."

None of these requirements differ a great deal from what was needed or sought for the past 50 years. Especially the "academic credentials." Nowhere does it require studies in administration, degrees in management, or other evidence of educational preparation.

After studying the history and development of higher education administration, through the growth period, both in size, complexity and sophistication, the question needs to be asked again: Is higher education administration becoming a profession— are the leaders of our universities trained in "a vocation requiring knowledge of some departments of learning or science?" (Rand McNally definition of a profession). Is the next generation going to represent people trained as administrators, rather than academics? Public opinion and the literature review of higher education say it is. Practical and current indications say no—at least not on the academic side or at the level of the president. There is a preponderance of professional types on the service side of the organizational chart and they may eventually extend to the level of the Board of Regents, Legislature and the governor.

However, the other side appears to be staying with the status quo. A review of the "Bulletin Board" section of The Chronicle of Higher Education supports this contention. The primary requirement for deans and department heads is still a scholarly faculty background and is carried through to the position of president. Except for small, private, special institutions, most schools want to promote the academic image as the prime focus. The day where the department of mechanical engineering hires a non-mechanical engineer graduate of higher education administration for department head, does not seem to be nearing. As Provost Neil L. Rudenstine of Princeton University was quoted in The Chronicle of Higher Education, "I don't think you can be an academic administrator unless you are first an academic...I think it would be odd to start out trying to be an academic administrator." (40)

It appears that in the future the requirements for president will continue to be that of academician, but with specific traits to meet the challenges of both internal and external forces. The primary concerns will continue to be the dealing with "competition between groups or individuals for power and leadership." This quote is the definition of politics from the Webster dictionary. Therefore, the image of the next generation of presidents is not the professional administrator, but the scholar/politician.

Conclusion

In summary, higher education administration will need to change course in the next decade. Historically, it has paid little attention to the internal and external factors influencing its environment. Traditional methods of academic administration were adequate for almost a century of growth. Today, however, higher education is being challenged by insufficient financing, outdated curricula, ineffective use of resources, and declining enrollments. To overcome these odds, it may need to become less specialized, and more diversified at both the individual and curriculum level. This must be reflected in the knowledge available and required by all educators, since these professional skills may be necessary for survival.

The knowledge of what principals value in teachers is important to both the teacher and the principal.

**Principals' View of the World: Identification of Valued Teacher Characteristics**

by Mary Lou Fuller and H.B. Slotnick

There was an aura of joy that delighted the children, and me, the principal.

With the words, an elementary principal described the best teacher who ever taught for her. Her observation is interesting, but it stops too soon: it doesn't describe those teacher characteristics that result in the "aura of joy." Stated more generally it doesn't identify those characteristics the principal valued in the described teacher.

The study examines elementary principals' perceptions of good teachers. It was a study designed to determine what elementary principals value in teachers. This information is important because of the impact principals' values have on a variety of areas within education.

The knowledge of what principals value in teachers is important to both the teacher and the principal. For practicing teachers, this information bears upon personal issues: teacher development, hiring, placement, evaluation, tenure and dismissal. For preservice teachers, the issues bear on admission policies (e.g., What personal characteristics are to be sought?) and curriculum (e.g., What skills should [can] preservice teachers be taught?)

For principals, knowledge of those issues allows development of self-awareness and makes explicit the issues under consideration when working with the people they supervise.

**Review of Literature**

She treats each child as someone special and tries to make learning a very special experience for every student.

Dr. Mary Lou Fuller is an assistant professor at the Center for Teaching and Learning at the University of North Dakota, Grand Forks. Dr. H.B. Slotnick is an associate professor at the School of Medicine, University of North Dakota, Grand Forks.

The quote beginning this paper spoke of a teacher's enthusiasm—this one speaks of warmth and humanization of instruction—both hallmarks of effective teachers.

The research uses labels such as "good," "effective," and "superior," and tends to look at collective behavior patterns. There is very little literature dealing with the best: Those teachers whose exceptional abilities set them apart and who truly deserve the Master Teacher designation.

In examining elementary principals' Tuckman found that they appear to prize teachers who are warm, accepting, highly organized and creative (1977). These characteristics are also cited in the effective teacher research with this body of literature identifying additional specific behaviors as well. Some of these specific behaviors are personal interest in students, willingness to listen to students (Gears, 1943); warmth, consideration, caring (Cogan, 1958; Tikunoff, Berliner and Rest, 1975; Reid, 1982); and enthusiasm (Mastin, 1965; Posenhine and Furst, 1973).

Hammack (1985, p. 315) classified the attributes of effective teachers under the categories of personality and intellectual traits.

**Personality Traits.** Effective teachers appear to be those who are, shall we say, "human" in the fullest sense of the word. They have a sense of humor, are fair, empathetic, friendly, enthusiastic and more democratic than authoritarian. Warmth, enthusiasm and humanness are important considerations when it comes to figuring out what it is that contributes to the psychology and behavior of effective teachers. However, these qualities are practically useless possessions if they are not accompanied by certain intellectual abilities.

**Intellectual Traits.** These abilities include understanding the use of teacher expectations (Brophy and Goode, 1973); knowing the subject matter, good communications skills (Bar, 1929); and recognizing and dealing with students' needs. While intellectual traits are essential to being an effective teacher, such individuals are nevertheless student-oriented as opposed to subject-oriented (Brophy, 1980).

Another way of looking at personality traits and intellectual skills is to examine what good teachers are and what they do. Using this framework, Olivia and Hanson developed Florida's 23 Essential Generic Competencies, a list divided into five general classes: communications skills, basic knowledge, technical skills, administrative skills and interpersonal skills.

In summarizing the research, Hammack (1986, p. 326) notes the repetition of certain effective teacher characteristics: ""Current research findings allow us to say that certain patterns of teacher behaviors are more likely to be associated with greater frequency among teachers who are effective or relatively as the case may be..." These patterns include a warm attitude with him but reasonable expectations, enthusiasm, knowledge of subject area, responding to students as individuals, providing study guidelines, encouraging and challenging, giving appropriate feedback, maintaining positive rapport, and remaining flexible.

The above traits appear to be exemplified by the description of the following teacher:

He was sympathetic, intelligent, and had a great sense of humor! His quick smile and relaxed mannerisms seemed to put his students at ease. His concern was genuine and students responded to his teaching. He would spend hours developing the curriculum to meet each student's needs.

*Educational Considerations, Vol. 13, No. 1, Winter 1986*
Given the observations in the literature, then, our general research question can be expanded to the following:

1. How do principals characterize "good" teachers?
2. How do principals characterize the "best" teachers?
3. Do principals perceive best and good teachers as sharing common characteristics?
4. How do principals' perceptions compare with those in the literature?

Materials and Methods

Sample. Respondents in this study were elementary principals attending the 1984 North Dakota Elementary School Administrators meeting. Continuing education courses are offered as part of the annual meeting, and students from two of those classes were invited to participate in this study. Demographic information including age, gender, and years of experience as a principal was collected from each respondent.

Instrument. An open-ended instrument was distributed to all participants. This format allowed respondents to identify attributes of importance to them rather than selecting descriptors we provided. Descriptors which may or may not reflect how they felt. An open-ended format meant some attributes might be overlooked by respondents, but we accepted this limitation intending that our results would "estimate the lower bound" of attributes important to principals.

In identifying the best teacher, we asked respondents to recall a specific individual, providing demographic information about this person (gender, age, grades taught), and writing a description of them. The description was subjected to content analysis producing the lists of attributes we sought.

A more "objective" approach was used to identify "good" teachers; the principals listed 10 attributes of good teachers, and reviewed the list in the same manner as the description of the "best" teachers.

The analytic strategy used in both cases identified all attributes the principals nominated, and then tabulated the number of respondents listing each. Finally a score test identified attributes mentioned often enough to represent the principals' views of that teacher group (Slotnick, 1982): We used the rule of thumb that any attribute mentioned by half or more was "definitely" characteristic of the teacher group, and any mentioned by one-fourth or more was "probably" representative. Attributes mentioned less often were considered idiosyncratic to either the teacher described or the principal responding.

Results

Sample. Fifty-two of the 60 persons eligible completed questionnaire (87 percent). Thirty-three of these persons were male and 19 female, and 79 percent administered schools with 400 or fewer students (the median school size was 275 pupils). The median age for the respondents was 43.03 years, and the median years of experience as a principal was 8.71. All had elementary school teaching experience before becoming principals.

Best Teachers. While the age distribution for best teachers indicated approximately equal numbers from age 20-24 to 35-39, the experience distribution was more leptokurtic (see Figure 1): While best teachers were likely to be between 20 and 39 years of age (a 20-year spread), most had 5-14 years of experience. The proportion of men nominated increased from the primary grades to grades 6-8. This probably reflects more men teaching in the higher grades than in the primary grades. (The chi square = 8.8889, df = 2, is significant at p = .0001.)

Best vs. Good Teachers. Thirteen of the 84 attributes nominated as characteristics of good teachers were listed by 25 percent of principals responding. In the content analysis, attributes of best teachers, 10 of 88 attributes met the X-25% criterion. Table 1 shows the overlap of attributes of good and best teachers with six of 17 attributes meeting criterion in both groups. Good teachers were characterized by seven additional nominations, best by four. In the former case, the attributes dealt with the teacher generally, while the latter typically described the teacher's one-to-one interaction with students.

actions with some other person. The common attributes are a collection of both general and those concerning one-to-one interactions.

**Discussion**

**Sample.** While the response rate was high (87 percent), the lack of random sampling means that caution must be used in generalizing the findings reported here.

**Instrument.** No problems were encountered in data collection and analysis; respondents had no difficulties understanding what was expected of them, in responding to both the prose (best teacher) and the listing (good teacher) questions.

Fewer attributes were nominated for best teacher than good teacher, and about 15 percent of the attributes for each group reached the 25 percent criterion. While it is possible the 84-to-68 advantage for good teachers reflects differences in instructions given to respondents, the requirement that items be nominated by 25 percent or more to be considered in further analysis meant that attributes retained were genuinely important without regard to the question's format.

**Question 1. How do principals characterize “good” teachers?** Attributes (Table 1) of good teachers tended to fall in two general categories: general professional skills (e.g., communications), and personality traits (e.g., sense of humor). Good teachers must have mastered basic professional skills and have certain personality attributes which facilitate working with people (e.g., a sense of humor).

**Question 2. How do principals characterize the best teachers?** Items attributed solely to the best teachers included enthusiasm, concern for the individual, good rapport with parents, good rapport with students, and new ideas. Apparently, some of the characteristics of the good teacher are prerequisite for the best teacher qualities. Expertise and knowledge must be mastered before much time and energy can be spent on developing new ideas; a sense of justice, fairness and honesty are prerequisites for an appreciation of the individual; a sense of humor and a positive outlook are important factors in developing enthusiasm; and communication skills and an appealing personality contribute to establishing good rapport with parents and students. The feature underlying three of the four attributes is the teacher's working with persons as individuals.

**Question 3. Do principals perceive best and good teachers as sharing common characteristics?** Some attributes are common to both groups: caring and concern; willingness to go the extra mile; organization; creativity; rapport with staff. While some of the good teacher characteristics involve basic professional skills (expertise and knowledge, discipline and community skills) only one item in the common group (organization) might be categorized this way, and none of the best teacher traits deals with basics. Apparently, basic professional skills are mastered before a teacher enjoys the "best" designation.

**Question 4. How do principals' perceptions compare with those in the literature?** This is important because the literature on effective teachers is authored primarily by persons (such as educational psychologists) who are not elementary principals. This difference in perspective means that, while principals take a relatively broad look at their teachers (e.g., Do children seem to learn in the classroom?), How much administrative energy is required to supervise the teacher?, How does the teacher deal with others such as parents and other teachers?), the educational psychologists' view is much more focused on learning and learning outcomes (e.g., Rosenshine and Furst, 1973). Hamachek (1965, p. 326) sees the commonalities in the effective teacher literature as:

- warm attitude with firm but reasonable expectations,
- enthusiasm,
- knowledge of subject area,
- responding to students as individuals,
- providing study guidelines,
- encouraging and challenging,
- giving appropriate feedback,
- maintaining positive rapport, and
- remaining flexible.

First, the research literature identifies having a “warm but firm attitude” which appear in the principals’ two attributes of good teachers: Such teachers are just, fair, and honest, and have a pleasing personality. We see warmth as deriving from a pleasing personality and firmness from being just and fair—demanding the appropriate levels of performance and behavior from everyone.

Second, “reasonable expectations” overlapped the principals’ observation that good teachers have expertise and are knowledgeable. Such expertise allows them to “know” the capabilities of their students, and thus to hold reasonable expectations for them. This expertise comes from knowing both the developmental capabilities of children and the nature of the educational demands being made on them. Third, enthusiasm is a characteristic mentioned by both groups, though the principals see it as characteristic only of the best teachers.

Fourth, knowledge of subject matter is identified by both the literature and the principals as a characteristic of good teachers while fifth best teachers establish rapport with individual students. This corresponds to “responding to students as individuals” in the literature.

Sixth, in expressing concern for individuals, best teachers encourage and challenge their students, certainty, encouragement and challenge do not exhaust the ways in which best teachers demonstrate this concern, but then the...
literature's view is more narrow than the principals who made the initial observations.

Seven, giving appropriate feedback, as noted in the literature (an aspect of communication skills) is an attribute of good teachers. Similarly, communication skills could also cover another of the literature's points, providing study guidelines.

The literature also noted that effective teachers maintain positive rapport with their students, an attribute similarly noted for best teachers.

Finally, flexibility is noted in the literature, but not identified as such by the principals. It is possible that flexibility is covered by other attributes (e.g., going the extra mile—as attributed to best teachers: expertise—as when a teacher tries something new).

A question remaining is whether teachers and principals agree on the characteristics of effective teachers. Grant and Carvell (1980) present evidence showing how teachers and principals agree on "evaluation criteria," defined to include desirable behaviors and attributes. Their findings encourage us to believe that the attributes identified here would also be valued by teachers.

This information can be used by principals in a variety of ways. First, it could help in the development of an awareness as to their individual values, and the implementations of those values. Related (and second), in-service programs might help principals identify their personal values, and determine the appropriateness of those values (e.g. by comparing them to the literature, by comparing them to the goals of the school district). Third, because some of the desirable teacher characteristics are teachable, a principal can develop an instructional plan of action that would encourage teachers to develop in those areas. Also, a principal, when employing new personnel, could be cognizant of personal and professional traits characterized by good teachers. Colleges of education would do well to be aware of the values of the future administrators of their preservice teachers and inform their students accordingly.

Given the data and procedures described in this paper, we have drawn the following conclusions.

1. Elementary principals view the attributes of good teachers as including basic professional skills and positive personality traits.
2. Three of the four attributes of best teachers concern working with individuals while the fourth describes enthusiasm.
3. They also see attributes common to both "good" and "best" teachers as a mixture of those described in (1) and (2).
4. Elementary principals' perceptions of the attributes of "good" and "best" teachers generally agree with the effective teacher literature.

Perhaps one of the principals described best teachers succinctly when he said:

Her pupils would rather be in school than at home.

Current professional discussion of curriculum and instruction issues is dominated by a technological curricular orientation.

Movement Away from a Technological Conceptualization of Curriculum

by Sandra J. LeSourd

Current professional discussion of curriculum and instruction issues is dominated by a technological curricular orientation. Instructional planning and implementation are characterized by procedures believed to be effective in bringing about manifest signs of learning. Some implicit assumptions can be identified in the technological conceptualization. One assumption is that learning proceeds best in an ordered progression. Another is that the occurrence of desired learning can be detected. Finally, efficiency is the assumed primary rationale for the methods of design and delivery of instruction.

Technological Conceptualization

Curriculum materials and practices which exemplify the technological conceptualization are common in schools. Entire descriptions of intended teaching and learning consist of a set of precise specifications of instructional routine and sequence. A main component of a technical curriculum design is the state of behavioral objectives or performance competencies. Deliberately executed instructional sequences are planned to ensure progress toward objective or competency attainment. Learning is deduced from students' ability to perform the behaviors stated in the objectives. A system of measurement, such as a test, is necessary. In the technological conceptualization, learning is conceived as a progression through discrete, sequential steps. Students' mastery of precisely specified tasks is regarded as the ultimate aim of teaching.

Educators, who subscribe to the technological conceptualization, view the curriculum as a mechanical system controlled by the aim of efficiency. Primary attention is devoted to the link between the means of instruction and the often unquestioned, discrete skills which are cited as the intended ends of instruction. Estimation of the value of the objectives as worthy educational ends is not a priority in technological curricular considerations. The fundamental paradigm is scientific and psychological, not humanistic and philosophical.

Tyler's seminal work in curriculum design provided the foundation for the scientific, technical conceptualization (1950). Tyler recommended a planning procedure which emphasized the relation of means to ends. His simply-stated steps including clarification of purpose, selection and organization of supporting learning experiences, and evaluation to determine if purposes are achieved, provide a basic framework for a technological procedure. Recent work in instructional system design represents amplification and refinement of the means-ends orientation (Gagne and Briggs, 1979). The strategies of instructional system design introduce a high degree of precision using psychological learning theory and concomitant instructional technique as the base for managing learning.

Rationale for Technological Conceptualization

There are plausible pragmatic explanations for the popularity of the technological conceptualization. For example, concurrent development of psychometrics as a science enabled precise statement and measurement of learning outcomes. Clearly, reliance upon proof that means have effectively led to ends requires valid and reliable measurement tools.

Another contributing explanation may be derived from the conservatism of the recent national sociopolitical climate. There is an apparent public demand for knowledge of teaching results in subjects which are interpreted basic to functional citizenship (Herzinger, 1981). A systematic curricular design with explicit specifications of exact skills and knowledge to be learned, and proof that the specified learning has occurred, is a convenient response to the public request for accountability in education.

Aside from the professional expertise of societal attitudes of the time, an explanation drawn from deep and lasting sources should also be entertained. Fundamental ideological beliefs are inherent in the assumptions of the technological conceptualization. The rationale for the operational procedures of technical curricular design illustrates endemic precepts of a scientific culture. Western reason and explanation depend upon knowledge of what is real. Real phenomena are expected to be observable or verifiable. In addition, the existence of orderly relationships among real phenomena is assumed. A common relationship, which is sought repeatedly for its explanatory power, is the order of cause to effect.

The conviction that phenomena which are verified can be regarded as real is consistent with the tradition of logical positivism (Hempel, 1933). The domination of this ideological tradition in the culture is commensurate with the prominence of the technological curricular approach. Materials and classroom instruction of the technological curriculum age exemplify attempts to make learning verifiable. Educators assume the phenomenon called learning can be demonstrated by the learner, observed by the teacher, and verified through assessment. The behavioral and skill performance aspects of schooling are emphasized to make verification possible. It is believed that effective measurement instruments provide proof of the existence and degree of learning. Educators' attempts to make learning manifest resemble the cultural aspiration to verify reality.

A second characteristic of the western system of rationality is the assumption that phenomena are ordered and
that the order can be discovered and described. This cultural precept is represented in means-ends curricular design. Instructional designs, the means, are conceived as causal agents in the production of test results, which are the ends of instruction. Thus, educators affirm their belief in the cause-effect relationship. If reality can be understood by description of events which bring about certain other events, then so can learning. In fact, the direct cause-effect relationship between identifiable variables is a statement of logic which is habitually both in and out of school. It is basic to the methods of scientific investigation which control professional inquiry into the universe of reality.

**Teachers' Commitment to the Ideological Rationale**

If we accept the proposal of a link between the tenets of instruction and the operation of a technological curricular conceptualization, we may question whether teachers share a commitment to those tenets. Does the thought that education in practice is a reflection of the convictions of teachers represent a valid presumption? It seems reasonable to expect to detect the tenets of logical positivism in the thinking of teachers who customarily implement means-ends curricular designs. Presumably, good instruction is more likely if curricular rationale and teacher beliefs are similar.

To conduct an informal consideration of the correspondence between curricular precepts and teacher beliefs, I administered an ideological questionnaire of my own design to 15 in-service teachers who were enrolled in a graduate course in curriculum. During class discussion the teachers reported using behavioral objectives, controlled management of skill practice, and frequent measurement of learner progress. They shared a history of implementers of means-ends curricula in various subjects and at various grade levels.

The responses to the questionnaire suggest some ambiguity in the group. All the teachers agreed with a statement that there is a direct link in reality between the occurrence of observable events and some preceding events. Thus, an acceptance of the notion of relationship between events was uniformly supported. However, the uniformity of the group was not maintained in reference to other questionnaire items. Seven of the 15 teachers agreed that order among the elements of reality can be discovered, while five responded that reality is controlled by forces which are beyond human understanding. Eight agreed with the suggestion that events have rational causes, a defensible basis for curriculum design. While the teachers in the class supported a belief in order between events, the group was less inclined to agree that the order could be discovered or that it should constitute the rationale for curriculum.

They all gave some indication of belief in an ordered universe, but some did not accept the notion as verifiable or as a suitable guide for curriculum practice.

Two of the 15 teachers agreed with a statement that schools should convey only knowledge which is verifiable. Apparently, the majority of the teachers in the class view worthwhile knowledge as including more than the observed elements of reality. This leaves the curriculum open to subject matter which does not satisfy logical positivism's criterion of verification.

Despite their reservations about some tenets expressed in the questionnaire, the teachers claimed to be active practitioners of technological curricular procedures. The questionnaire responses suggest the hypothesis that teachers may carry out operations which are not completely supported by their personal ideological stance.

**Movement to Alternate Conceptualization**

The technological conceptualization has sustained an impressive period of entrenchment in American education. One explanation for its popularity may derive from the close relationship to the ideological tradition of logical positivism. A dramatic break from the technological conceptualization and proposal of an alternate-envisioned approach would require substitution of a new rationale. The contention that the current technological rationalization has roots in the cultural ethos implies that alternate justifications will come from the same source.

One recent presentation of an alternative to the technological emphasis turns attention to an appeal for more comprehensive school learning (Eisner, 1982). Eisner criticizes the technological conceptualization for its strict governance of design and consequent limitation of content. He maintains that the means-ends priority, concentration upon basic literacy and numeracy requisites, and concern for confirmation of progress in discrete skills, have produced a narrow conceptualization of the substance of learning. The result is an inadequate education in the variety of forms of human endeavor which contribute to an intelligent life guided by the pursuit of meaning. Eisner presents an expanded version of curriculum which allows expression of meaning through multiple forms of representation which include the fine arts.

Critical reaction to the technical emphasis invites a philosophic examination of what learning is worthy of attainment (English, 1983). Decisions of this nature will require a search for value priorities. To be consistent with the hypothesized existence of a relationship between the means-ends rationale and the cultural dedication to logical positivism, an alternate conceptualization proposes a need for a new cultural foundation. It will be necessary to determine which cultural precepts will guide an alternate conceptualization of curriculum.

It is unclear whether there is a need for teachers to possess a strong positive conviction toward the tenets of a curricular conceptualization. Perhaps in the technological period, the prescriptive nature of instructional design has precluded teacher identification with the ideological tenets. Teachers may simply implement a means-ends plan regardless of the power of the rationale in their own thinking. Perhaps teachers are practitioners in an exclusive sense. Possibly, the rationalizations which influence the selection and design of learning experiences are irrelevant to the teacher's main task of actually conducting the experiences.
