Single and Sequential Applications of Anthem Maxx, Solstice, Acuron, Balance Flexx, Corvus, Halex GT, Verdict, Sharpen, Glyphosate, and Atrazine in Irrigated Corn

R.S. Currie and P.W. Geier

Summary

A study was initiated near Garden City, KS, in 2016, comparing the weed control of several herbicide treatments and their sequential application for weed control in irrigated corn. Quinoa and common sunflower control was excellent. All sequential herbicide treatments provided excellent control of kochia, velvetleaf, Palmer amaranth, and green foxtail. Single applications at the V4 stage, although still good, showed a reduced level of Palmer amaranth and green foxtail control compared to sequential treatments.

Introduction

Acuron (metolachlor + atrazine + mesotrione + bicyclopyrone), Anthem Maxx (pyroxasulfone + fluthiacet), Balance Flexx (isoxaflutole), Corvus (isoxaflutole + thiencazone), Halex GT (metolachlor + glyphosate + mesotrione), Sharpen (saflufenacil), Solstice (fluthiacet + mesotrione), and Verdict (saflufenacil + dimethenamid) have all been shown to provide excellent broad spectrum weed control in irrigated corn. Head-to-head comparisons of these tank mixes with local weed populations are needed. Therefore, it was the objective of this trial to compare the weed control of these products under statistically replicated conditions.

Experimental Procedures

An experiment conducted at the Kansas State University Southwest Research-Extension Center near Garden City, KS, evaluated the efficacy of single and sequential herbicide applications in corn. The entire plot area was over-seeded with foxtail, crabgrass, and Palmer amaranth, as well as the domestically cultivated sorghum 'Rox orange,' quinoa, and sunflowers. These serve as proxies for their wild relatives, shattercane, lambsquarters, and wild sunflowers, respectively. Treatments were applied preemergence followed by early postemergence (V4) or postemergence (V8) or as early postemergence (V4) alone. All herbicides were applied using a tractor-mounted, compressed-CO₂ sprayer, delivering 20 GPA at 3.0 mph and 30 psi. Soil was a Ulysses silt loam with 1.4% organic matter, pH of 8.0, and cation exchange capacity of 18.4. Plots were 10 by 35 feet and arranged in a randomized complete block design with four replications. Visual weed control was determined July 13, 2016, which was 27 days after the V8 applications (DAPO). Grain yields were determined September 20, 2016, by mechanically harvesting the center two rows of each plot and adjusting the weights to 15.5% moisture.

Results and Discussion

Quinoa and common sunflower control was 100% regardless of treatment at 27 DAPO (data not shown). All herbicides provided excellent control of kochia, velvetleaf, Palmer amaranth, and green foxtail when applied as sequential treatments. Single applications at the V4 stage, although still good, did not control Palmer amaranth and green foxtail as well as the sequential treatments. Herbicide-treated corn yielded 179 to 197 bu/a but did not differ between treatments. Untreated corn yielded 188 bu/a (data not shown).

Table 1. Application information

Application timing	Preemergence	V4 corn	V8 corn
Application date	May 6, 2016	June 2, 2016	June 16, 2016
Air temperature (°F)	60	76	79
Relative humidity (%)	55	47	46
Soil temperature (°F)	57	64	72
Wind speed (mph)	8 to 10	4 to 6	7 to 10
