Weed Control and Crop Tolerance in Inzen Grain Sorghum with Zest Tank Mixtures

Abstract
Although preemergence applications of Cinch ATZ provided excellent green foxtail control, it did not provide commercially acceptable levels of Palmer amaranth or crabgrass control. All postemergence tank mixes of Zest raised the level of control achieved by the preemergence applications of Cinch ATZ to excellent levels for these species. With the exception of the Huskie tank mix, which provided excellent Palmer amaranth control, all other postemergence programs provided only adequate control of Palmer amaranth, crabgrass, or green foxtail. Weed pressure of these species was extreme. Under conditions of extreme weed pressure, a foundation treatment of Cinch ATZ followed by a postemergence application would be needed for commercially acceptable levels of weed control.

Weed Control and Crop Tolerance in Inzen Grain Sorghum with Zest Tank Mixtures

R. Currie and P. Geier

Summary
Although preemergence applications of Cinch ATZ provided excellent green foxtail control, it did not provide commercially acceptable levels of Palmer amaranth or crabgrass control. All postemergence tank mixes of Zest raised the level of control achieved by the preemergence applications of Cinch ATZ to excellent levels for these species. With the exception of the Huskie tank mix, which provided excellent Palmer amaranth control, all other postemergence programs provided only adequate control of Palmer amaranth, crabgrass, or green foxtail. Weed pressure of these species was extreme. Under conditions of extreme weed pressure, a foundation treatment of Cinch ATZ followed by a postemergence application would be needed for commercially acceptable levels of weed control.

Introduction
Nonirrigated sorghum is often planted under less than ideal conditions, and germination of the crop is uncertain. Producers often want to delay investing more resources in a crop until a good stand has been achieved. Grass control is often the most expensive component of an herbicide tank mix. At present, no labeled herbicide supplies excellent postemergence grass control that allows the producer to first determine if a stand of sorghum has been achieved before investing in grass control. Zest (nicosulfuron) has been used with the trade name Accent for more than 25 years for postemergence grass control in corn. A naturally occurring weedy sorghum with resistance to nicosulfuron has been used to breed commercial sorghum hybrids that are resistant to this herbicide. Although properly used nicosulfuron can provide postemergence grass control, it has only modest utility in controlling broadleaf weeds and preventing future emergence of other grasses. The objective of this study was to determine how to augment Zest’s weed control in sorghum.

Procedures
An experiment at the Kansas State University Southwest Research-Extension Center in Garden City, Kansas, examined crop tolerance and weed control with Zest tank mixtures as either stand-alone or sequential treatments in irrigated acetolactase synthase-tolerant (Inzen) irrigated grain sorghum. Sorghum was planted June 19, 2014, and preemergence herbicides were applied the following day (Table 1). Early postemergence (stand-alone) and postemergence (sequential) treatments were applied on July
11 and July 28, 2014, respectively. All herbicides were applied with a CO₂-pressurized, backpack sprayer delivering 20 gpa at 3.0 mph and 27 psi. Soil was a Ulysses silt loam with 1.4% organic matter, pH of 8.0, and cation exchange capacity of 18.4. The entire experimental area was overseeded with a mixture of shattercane (rox orange), green foxtail, and crabgrass seed. The Palmer amaranth population was a natural infestation. Plots were 10 by 35 feet, arranged in a randomized complete block with four replications.

Sorghum injury was evaluated July 14 (3 days after early postemergence treatments) and August 1, 2014, (4 days after postemergence treatments). Weed control was determined visually on August 20, 2014, which was 61, 40, and 23 days after preemergence, early postemergence, and postemergence applications, respectively.

**Results and Discussion**

Although Inzen sorghum produced an excellent-looking grain crop, at the request of the DuPont Company — which provided the seed grain — yields were not determined. Although preemergence applications of Cinch ATZ provided excellent green foxtail control, it did not provide commercially acceptable levels of Palmer amaranth or crabgrass control (Table 2). All postemergence tank mixes of Zest raised the level of control achieved by the preemergence applications of Cinch ATZ to greater than 93% for these species. With the exception of the Huskie tank mix, which provided excellent Palmer amaranth control, no total postemergence program provided greater than 86, 73, or 88% control of Palmer amaranth, crabgrass, or green foxtail, respectively. Weed pressure of these species was extreme. Under conditions of extreme weed pressure, a foundation treatment of Cinch ATZ followed by a postemergence application would be needed for commercially acceptable levels of weed control. All treatments provided 100% control of shattercane seeded across the entire plot area.
